

What are the advantages of flying-capacitor booster?

The flying-capacitor booster is a high-efficient, low cost solution for solar inverter applications. The main advantages are the frequency multiplication, the lower semiconductor voltage, the lower voltage and current ripple, the lower switching losses, and the low EMI emission.

What is a flying capacitor booster?

In this topology the additional voltage levels are synthesized by capacitor, so-called flying capacitor. In three level case the voltage of the flying capacitor is the half of the output voltage. This capacitor can offset the output voltage with in positive and negative direction. The three level Flying Capacitor Booster can be seen on Figure 1.

What are the advantages and disadvantages of flying-capacitor booster topology?

The main advantages are the frequency multiplication, the lower semiconductor voltage, the lower voltage and current ripple, the lower switching losses, and the low EMI emission, while the enormous DC-link capacitor can be also eliminated. As every other topology the flying-capacitor booster topology has some challenges also.

What is the commutation loop of a flying capacitor booster?

Its main role in the commutation loop is to offset the two outer semiconductors from each other. With this offset the three-level flying-capacitor booster can be considered as two standalone boosters, in which the outer one's commutation loop includes the DC-link capacitor, the outer diode, the flying capacitor and the outer switch.

What is a three level flying capacitor booster?

With this offset the three level flying capacitor booster can be considered as two standalone Boosters, where the outer one's commutation loop includes the DC-link capacitor, the outer diode, the flying capacitor and the outer switch. The inner commutation loop includes the flying capacitor, the inner diode and the inner switch.

How Booster is used in a solar inverter?

To achieve this, not only the inverter but also the Booster stage have to be low cost and high efficient. Two and three level Boosters are commonly used in solar inverters. The three level solutions are able to decrease the voltage stress on the semiconductors and the output voltage ripple, therefore the inductor size can be decreased.
