

What happens if capacitance and network inductance resonant?

Capacitor capacitance and network inductances may form a parallel resonant circuit, where harmonic currents may be as much as 20 times the normal level. Should the natural frequency of the resonant circuit match an existing harmonic frequency, the current distortion caused by resonance leads to further voltage distortion.

What are automatic capacitor banks?

Automatic capacitor banks are used for centralized power factor correction at the main and sub distribution boards. Power factor correction means that reactive power charges imposed by electricity utilities can be avoided.

What is compensating reactive power?

Compensating reactive power means supplying this power in place of the distribution network by installing a capacitor bank as a source of reactive power  $Q_c$ . This offers a host of advantages: savings on the sizing of electrical equipment because less power is required increase in the active power available on the transformer secondary

Why do we use capacitors?

We use capacitors to supply the reactive power to the inductive receivers and to raise the displacement power factor ( $\cos \phi$ ). Summary When an energy supplier supplies reactive power, it overloads the lines and transformers.

What are the different types of capacitors?

Four "types of capacitors" are proposed, depending on the level of harmonic pollution ( $Sh/S_n$ ): Standard type: voltage 400 V H type: reinforced voltage 440 V or 500 V SAH type: reinforced voltage + anti-harmonic inductive circuit FH type: harmonic filter. Survey of the installation by the Audit & Troubleshooting Department.

What types of capacitors can be used to protect a network?

ENERDIS offers solutions adapted to the level of pollution: Standard 400 V capacitors and reinforced 440V or 500 V capacitors recommended for networks with low or average pollution Capacitors with an anti-harmonic inductive circuit for polluted networks Protecting capacitors with anti-harmonic inductive circuits
