What is single capacitor coupled wireless power transfer (SC-CPT)?

Single capacitor coupled wireless power transfer (SC-CPT) is not only cost-effective but also eliminates the impact of cross-coupling capacitance present in traditional CPT systems, making it more suitable for wireless charging in two-dimensional mobile devices.

Why do wireless charging systems use resonant inductors and external capacitors?

Resonant inductors and external capacitors are also used to resonate with the capacitive coupler structure for each side of the wireless charging system. Herein, the external capacitors are typically used due to low coupling capacitance of the system.

Can resonant capacitors be used for wireless charging?

Capacitive power transfer (CPT) technology has become a promising alternative solution for wireless charging applications. This paper proposes a novel coupler design to form a resonant capacitor by inserting dielectric material between two bent metal plates for each primary and secondary circuit.

What is a high power resonance capacitor?

High-power resonance capacitors are an important component in magnetic resonance using wireless power transfer EV charging systems. This is because a high-accuracy resonance circuit with high withstand voltage is required for efficient wireless transfer of a large amount of power in a short time.

Can coupling capacitors achieve stable output power and constant transmission efficiency?

Therefore, achieving stable output power and constant transmission efficiency under different coupling capacitors is a significant challenge. CPT systems generally operate at frequencies around megahertz, and the passband width of the system's compensation network is typically very narrow.

What type of charging infrastructure is needed for autonomous driving?

An especially promising type of charging infrastructure is wireless power transfer systems which enable non-contact charging. Furthermore, wireless power transfer is also an essential technology for practical implementation of autonomous driving.

This paper proposes a new topology-reconfigurable capacitive compensation network, aiming to achieve the energy encryption of the contactless charging for multiple electric vehicles (EVs). The proposed variable topology of compensation network consists of an $M \times N$ capacitor matrix, where capacitors can be connected either in series or in parallel by controlling switches. Then, the ...
