

Can low-temperature lithium-ion batteries be managed?

Feasible solutions for low-temperature kinetics have been introduced. Battery management of low-temperature lithium-ion batteries is discussed. Lithium-ion batteries (LIBs) play a vital role in portable electronic products, transportation and large-scale energy storage.

Is there a framework for low-temperature fast charging of lithium-ion batteries?

A three-electrode battery is constructed for study. A low-temperature charging framework is developed. This paper proposes a novel framework for low-temperature fast charging of lithium-ion batteries (LIBs) without lithium plating. The framework includes three key components: modeling, constraints, and strategy design.

Can high-throughput experiments be used in the research of low-temperature batteries?

Although many efforts have been made in the research of low-temperature batteries, some studies are scattered and cannot provide systematic solutions. In the future study, high-throughput experiments can be used to screen materials and electrolytes suitable for low-temperature batteries.

Is a low-temperature battery charging strategy reliable and feasible?

These observations collectively suggest that the low-temperature charging strategy proposed in this study is reliable and feasible. Another important validation concerns the absence of lithium plating. Fig. 10 (H) illustrates the results for the graphite negative potential of the three-electrode battery.

What is a systematic review of low-temperature lithium-ion batteries?

In general, a systematic review of low-temperature LIBs is conducted in order to provide references for future research. 1. Introduction Lithium-ion batteries (LIBs) have been the workhorse of power supplies for consumer products with the advantages of high energy density, high power density and long service life .

How does low temperature affect battery performance?

At low temperature, the high desolvation energy and low ionic conductivity of the bulk electrolyte limit the low-temperature performance of the LMBs . Such processes play important roles in deciding the low-temperature performances of batteries .

To address the issues mentioned above, many scholars have carried out corresponding research on promoting the rapid heating strategies of LIB [10], [11], [12]. Generally speaking, low-temperature heating strategies are commonly divided into external, internal, and hybrid heating methods, considering the constant increase of the energy density of power ...

Although the battery system is generally equipped with a thermal management system to ensure that the battery works at an appropriate temperature [[5], [6], [7]], relevant experiments show that it often takes about

15 min for the existing thermal management system to safely heat the battery in a low-temperature environment to a suitable working temperature [8]. ...

(1) Improving the internal kinetics of battery chemistry at low temperatures by cell design; (2) Obtaining the ideal working temperature by auxiliary heating technology; (3) ...

This paper proposes a novel framework for low-temperature fast charging of lithium-ion batteries (LIBs) without lithium plating. The framework includes three key ...

Lithium difluoro (oxalate)borate (LiDFOB) is another well-known lithium salt used for improving low temperature battery characteristics [185]. However, it is proven that traditional electrolyte with LiDFOB has poor temperature performance [166]. Nevertheless, if this salt is combined with another electrolyte system, low temperature performance ...

When the temperature drops below 0 °C, the internal resistance of the battery increases rapidly and the available capacity decreases seriously, resulting in a significant decrease in the energy density and power density. And using the battery at low temperature accelerates battery aging [[1], [2], [3]].

More information regarding definitions (i.e., generation 3b, generation 4, etc) can be found in SET-Plan Action 7, Implementation Plan "Become competitive in the global battery ...

Initially, the impedance arc of the battery significantly expands as the temperature decreases, which is caused by the fact that the internal reactions inside the LIBs slow down in a low-temperature environment [3]. Furthermore, at identical temperatures, the impedance arc of the battery in the middle to low frequencies diminishes and then amplifies as ...

This challenge is further exacerbated by the lack of high power and low-temperature cycling data in the literature, with the majority of published low-temperature studies limiting the maximum discharge rates to C/5, C/10, or C/20 [[7], [8], [9], [10]]. At low temperatures, diffusion of Li<sup>+</sup> through the electrolyte, the SEI, and in the electrode materials slows [11, 12].

In this article, a brief overview of the challenges in developing lithium-ion batteries for low-temperature use is provided, and then an array of nascent battery chemistries are introduced ...

With the rapid development of smart clothing, implantable medical devices, artificial electronic skin, and other flexible wearable electronic devices, the demand for energy storage devices is escalating [1, 2]. Flexible zinc-ion batteries (FZIBs) are regarded as promising energy storage solutions, propelling the progress of emerging wearable electronic devices ...
