

What are thin film solar cells?

Thin film solar cells are favorable because of their minimum material usage and rising efficiencies. The three major thin film solar cell technologies include amorphous silicon (a-Si), copper indium gallium selenide (CIGS), and cadmium telluride (CdTe).

Are CIGS and CdTe the future of thin film solar cells?

CIGS and CdTe hold the greatest promise for the future of thin film. Longevity, reliability, consumer confidence and greater investments must be established before thin film solar cells are explored on building integrated photovoltaic systems.

1. Introduction

Are thin film solar panels reliable?

The reliability of thin film is questionable in comparison with the emergence and production of competitive and low-cost crystalline silicon solar panels.

How are amorphous thin film Solar Cells fabricated?

5.1. Amorphous Thin-Film Silicon (a-Si) a-Si solar cells, typically 1- μ m thick, are fabricated using a layered method starting with a silicon dioxide substrate and p-type tin oxide (SnO_2) contact. a-Si is deposited by decomposing silane gas (SiH_4), creating dangling bonds passivated by hydrogen.

What are the new thin-film PV technologies?

With intense R&D efforts in materials science, several new thin-film PV technologies have emerged that have high potential, including perovskite solar cells, Copper zinc tin sulfide ($\text{Cu}_2\text{ZnSnS}_4$, CZTS) solar cells, and quantum dot (QD) solar cells.

6.1. Perovskite materials

How can thin film technology improve reliability?

However, major approaches in thin films such as using more robust materials and cell architectures to improve reliability, and decreasing dependence on rare elements by creating new materials may allow for further market growth of thin film technologies.
