

What is the current direction of a battery?

In the circuit shown here the conventional current direction is from V2 to V1 and is equal to 3 Amp. I understand the theory. But, if I make this circuit with two batteries, according to the schematic the current (positive charge) leaves a positive side of one battery and goes through the positive side of the second battery.

Does 'provide twice the current' matter if a battery is connected in parallel?

The 'internal resistance' of each battery matters; when you put them in parallel, the internal resistances are effectively in parallel, and thus halved. Oh, and 'provide twice the current' should not be read as 'will always output twice the current' - current draw is still determined by the circuit connected.

What happens if two batteries are in parallel?

When two or more batteries are placed in parallel, the voltage in the circuit is the same as each individual battery. That is two, three, four or more 1.5 volt batteries in parallel will produce a voltage of 1.5 Volts! What happens when batteries are in parallel? How do you solve batteries in parallel?

How long can a battery run in parallel?

There's a sentence I really can't understand: Figure 1-73. Batteries in parallel, powering the same load as before, will run it for for about twice as long. Alternatively, they can provide twice the current for the same time as a single battery.

Does a battery provide twice the current?

The battery does not provide twice the current, two batteries provides the same current. Overall current is twice as you have two batteries instead of one.

How do you connect two batteries in parallel?

To join batteries in parallel, use a jumper wire to connect both the positive terminals, and another jumper wire to connect both the negative terminals of both batteries to each other. Negative to negative and positive to positive. You CAN connect your load to ONE of the batteries, and it will drain both equally.

he explains by saying imagine there's a guy walking around the circuit and you record the voltage rises and drops so +20 for a battery -10v and -10v for two resistors, but he has never done this with a parallel circuit let

There are two ways to wire batteries together, parallel and series. The illustration below show how these wiring variations can produce different voltage and amp hour outputs.

In ideal circuit theory, the parallel connection of two voltage sources results in an inconsistent equation, e.g., a 3V and 2V source connected in parallel, by KVL, gives the equation:  $3 = 2$ . In the real world, batteries are not ideal voltage sources; batteries can supply a limited current and the voltage across the battery does, in fact ...

Current direction would be from right to left because sources are connected in series opposing configuration, both the current will flow in the circuit in opposite direction and produce net effect to right because of larger magnitude of right source, and infact, current would flow from 120V source, completing the path for flow but that current ...

When current flows through two parallel wires in the same direction, the force  $F_m$  experienced by one wire is due to the magnetic field produced by the other wire and is attractive in nature.. In case of two beams of electrons moving in the same direction, in addition to  $F_m$  another force  $F_e$  (electrical and repulsive for two electrons) also acts.. Since  $F_m < F_e$ .
